

Table IA.1
Additional Deal Summary Statistics

This table reports additional deal level summary statistics for CDOs in our sample. $p10$ and $p90$ denote the 10th and 90th percentiles, respectively.

	N	Mean	Median	Std. Dev.	p10	p90
No. of Obligors	1109	130.76	122.00	62.69	62.00	210.00
Deal Size (\$M)	1096	39 .16	375.00	334.30	0.4	707.00
WAM	1109	6.1	5. 3	1.33	4.93	7.71
S&P SDR	67	0.361	0.359	0.120	0.200	0.503
Moody's SDR	67	0.334	0.332	0.110	0.22	0.439

Table IA.2**Correlation of Rating Changes**

This table reports the correlation matrix of directional rating changes. Reported are the time-series correlations for the percentage of directional rating changes at the monthly level from January 19 6 to December 2012.

	Rating Downgrade	Rating Unchanged	Rating Upgrade
Rating Downgrade	1		
Rating Unchanged	-0. 5	1	
Rating Upgrade	-0.160	-0.319	1

Table IA.3**Corporate Default Correlations Prior to 2007**

This table reports the matrix of default correlations from three model specifications considering time-varying credit ratings and/or time-varying default frailty. Reported are the pair-wise 5-year default correlation between two bonds of varying credit quality from January 19 6 to December 2006. Panel A reports the results of a model including only model frailty, Panel B reports the results of a model only including time-varying rating transitions, and Panel C reports the results of a model including both frailty and rating transitions drawn from their joint distribution. We draw 100,000 sample rating transition and frailty paths 60 months in length for each pair of bonds and calculate the default probability of each bond over the 60 month period conditional on its monthly default intensities, and denote the bond as defaulting if a random variable drawn from a uniform distribution with a range of [0,1] is less than the default probability of the bond. We then calculate the default correlation from these 100,000 realizations of bond default.

Panel A. Time-Varying Rating Transitions

Table IA.4**Corporate Default Correlations - Independently Drawn Frailty and Rating Change Paths**

This table reports the matrix of default correlations similar to Panel C of Table IV, with the exception that the frailty and rating transition paths are independently drawn. Reported are the pair-wise 5-year default correlations between two bonds of varying credit quality from January 19 6 to December 2012 (Panel A) and January 19 6 to December 2006 (Panel B). We draw 100,000 sample rating transition and frailty paths 60 months in length for each pair of bonds and calculate the default probability of each bond over the 60 month period conditional on its monthly default intensities, and denote the bond as defaulting if a random variable drawn from a uniform distribution with a range of [0,1] is less than the default probability of the bond. We then calculate the default correlation from these 100,000 realizations of bond default.

		Mean Reversion, κ	0.039 (0.0061)

Table IA.12**Corporate Default Correlations with Parameter Uncertainty**

This table reports the matrix of default correlations when incorporating uncertainty in the parameter estimates. Reported are the pair-wise 5-year default correlation between two bonds of varying credit quality from January 19 6 to December 2012 (Panel A) and January 19 6 to December 2006 (Panel B). Reported are the results of a model including both frailty and rating transitions drawn from their joint distribution. For each draw we draw each model parameter from a normal distribution with a mean equal to the point estimate and a standard deviation equal to the parameter's standard error reported in Table II. We draw 100,000 sample rating transition and frailty paths 60 months in length for each pair of bonds and calculate the default probability of each bond over the 60 month period conditional on its monthly default intensities, and denote the bond as defaulting if a random variable drawn from a uniform distribution with a range of [0,1] is less than the default probability of the bond. We then calculate the default correlation from these 100,000 realizations of bond default.

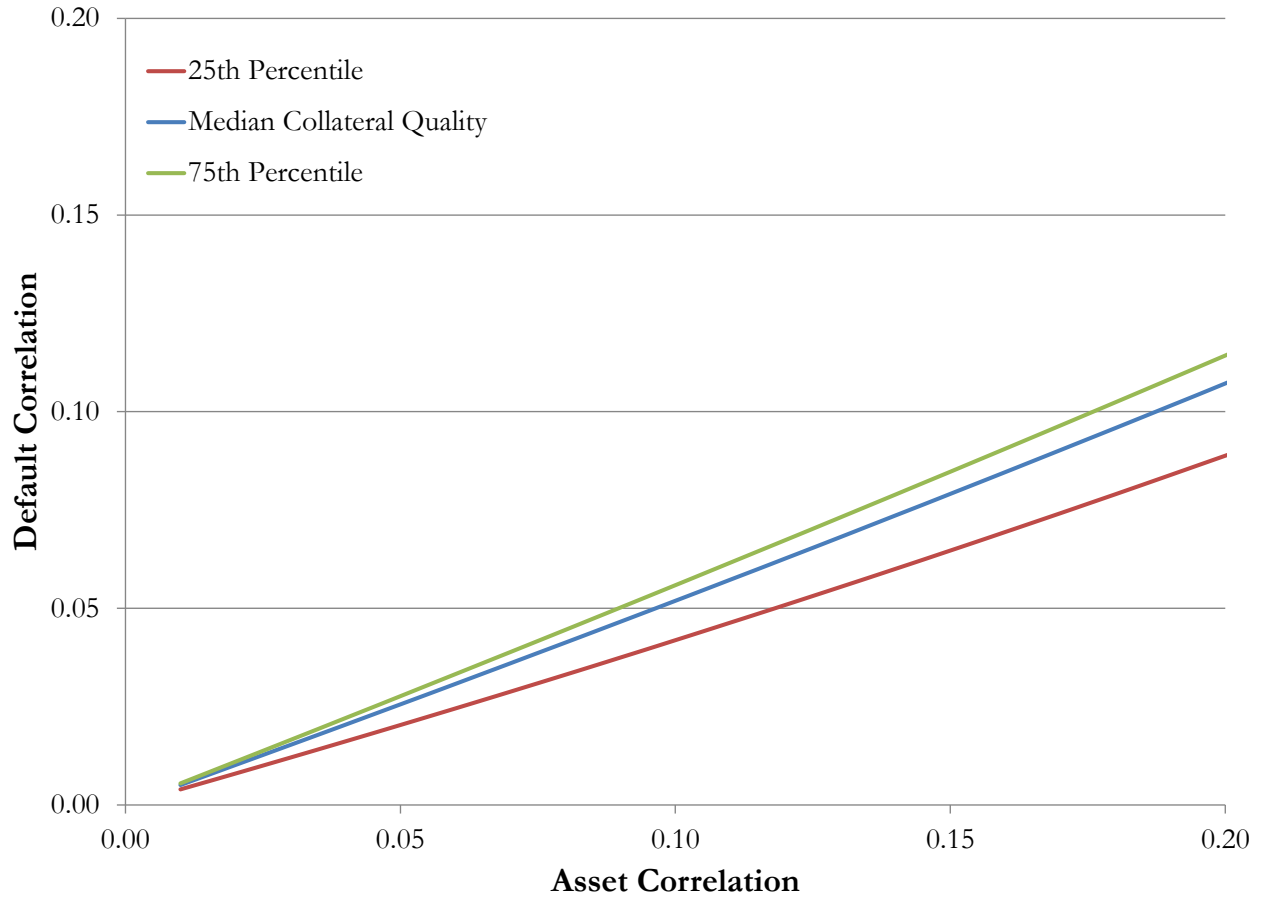

Figure IA.1

Asset Correlation versus Default Correlation

This figure illustrates the relationships between asset correlation and default correlation. The x-axis reports the asset correlation used as an input in the Gaussian Copula and the y-axis reports the average pair-wise default correlation from the simulated asset defaults. A pool of 122 assets, which corresponds to the median number of obligors in our sample of CDOs, was simulated 100,000 times for each asset correlation assumed. Reported are the mappings from asset correlation to default correlation when each assets probability of default is set to the 25th, 50th, and 75th percentiles of the average underlying collateral probability of default in our sample.

Figure IA.2

Corporate Bond Yield and Estimated Frailty Path

This figure illustrates the conditional mean of the frailty path from a hazard model fitted using the firm's credit rating lagged by 1 month (solid blue line) and the monthly corporate credit yield spread (dashed red line). 4,000 paths were drawn from a Gibbs sampler using the estimated coefficients from the fitted frailty and rating transition models reported in Table II. The path has been scaled by the appropriate scaling parameter, η . *Corporate Yield Spread* is the Moody's Seasoned Baa Corporate Bond Yield minus the 30-year Treasury Constant Maturity Rate, both provided by FRED.

Figure IA.3

Estimated Frailty and Rating Transition Paths for ABS Securities

This figure illustrates the conditional mean of the frailty path from a hazard model fitted using the ABS tranche’s credit rating lagged by 1 month (blue line) and the mean path modifying the base transition matrix (red line). 4, 00 paths were drawn from a Gibbs sampler using the estimated coefficients from the fitted frailty and rating transition models reported in Internet Appendix Table IA.5. Each path has been scaled by its respective scaling parameter, η .

Figure IA.4
Estimated Frailty and Rating Transition Paths for MBS Securities

This figure illustrates the conditional mean of the frailty path from a hazard model fitted using the MBS tranche's credit rating lagged by 1 month (blue line) and the mean path modifying the base transition matrix (red line). 4,000 paths were drawn from a Gibbs sampler using the estimated coefficients from the fitted frailty and rating transition models reported in Internet Appendix Table IA.1. Each path has been scaled by its respective scaling parameter, η .
